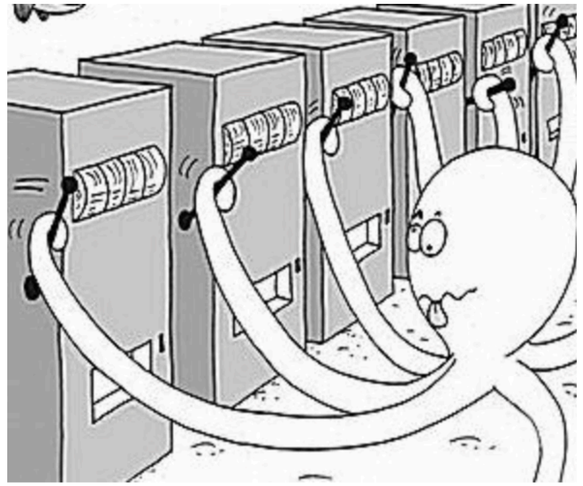
An introduction to Reinforcement Learning

28th of June 2022

Recap: Multi-armed bandits

Greedy action selection:

$$P(a_t = a) = \begin{cases} 1 & \text{if } a_t = \text{argmax}_a \; V_t(a) \\ 0 & \text{otherwise} \end{cases}$$



Epsilon-greedy action selection:

$$P(a_t = a) = \begin{cases} 1 - \epsilon & \text{if } a_t = \text{argmax}_a \; V_t(a) \\ \epsilon / N & \text{otherwise} \end{cases}$$

Softmax action selection:

$$P(a_t = a) = \frac{e^{V_t(a) \cdot \beta}}{\sum_{i=1}^{N} e^{V_t(a_i) \cdot \beta}}$$

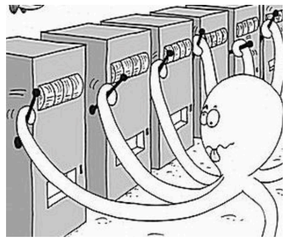
Action is governed by a **policy**:

$$\pi(a, s) = P(a_t = a \,|\, s_t = s)$$

Upper-confidence-bound (UCB) action selection:

$$P(a_t = a) = \text{argmax}_a [V_t(a) + c \cdot \sqrt{\frac{\ln t}{N_t(a)}}]$$

Perfomance comparison

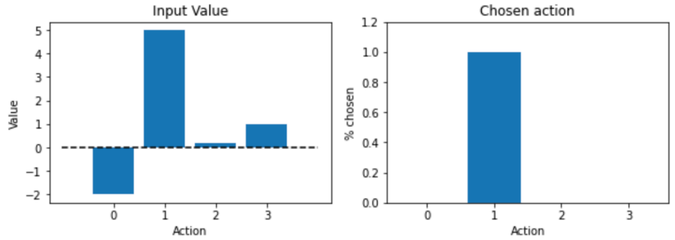


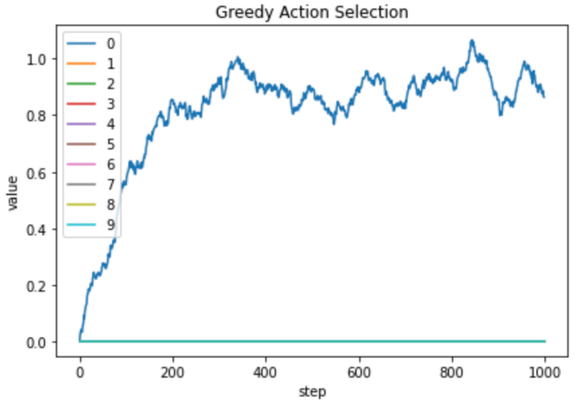
N arms = 10

N simulations = 1000

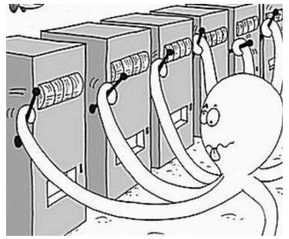
Greedy action selection:

$$P(a_t = a) = \begin{cases} 1 & \text{if } a_t = \text{argmax}_a \; V_t(a) \\ 0 & \text{otherwise} \end{cases}$$





Perfomance comparison

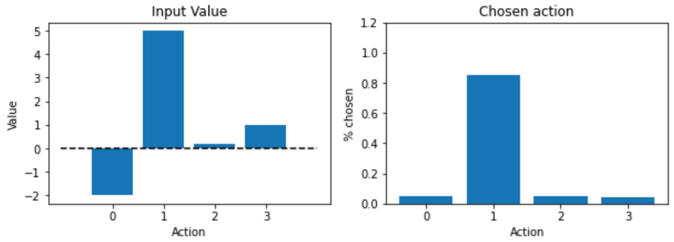


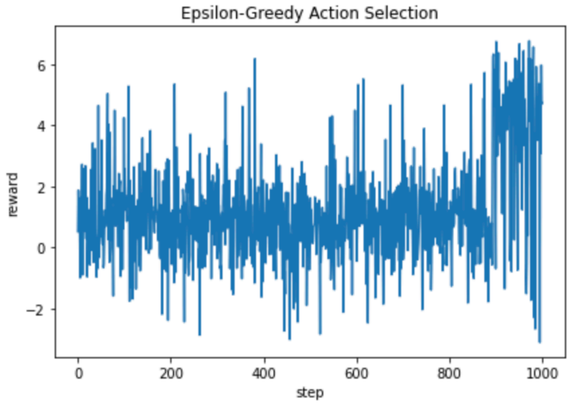
N arms = 10

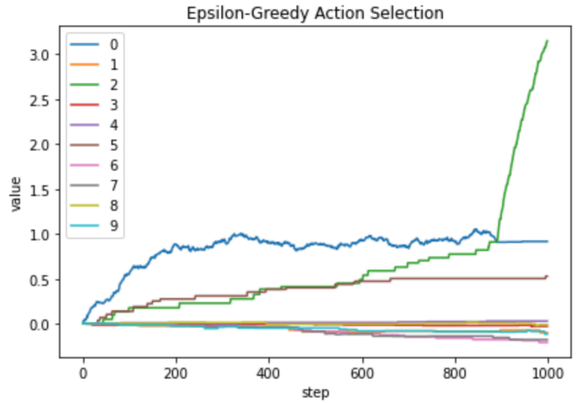
N simulations = 1000

Epsilon-greedy action selection:

$$P(a_t = a) = \begin{cases} 1 - \epsilon & \text{if } a_t = \text{argmax}_a \; V_t(a) \\ \epsilon / N & \text{otherwise} \end{cases}$$





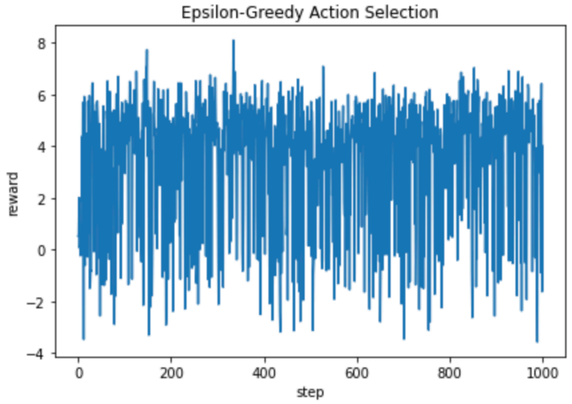


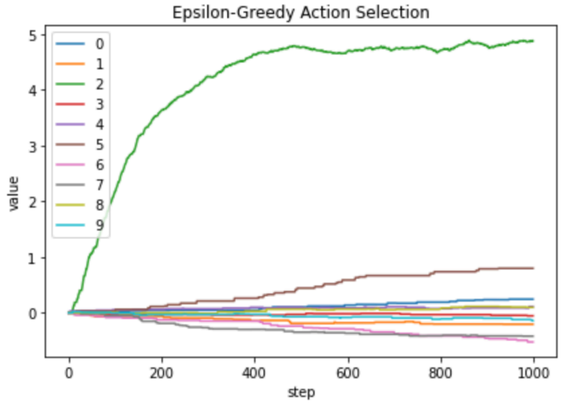
How will your choice of ϵ affect these plots? (Here: $\epsilon = 0.15$)

Perfomance comparison

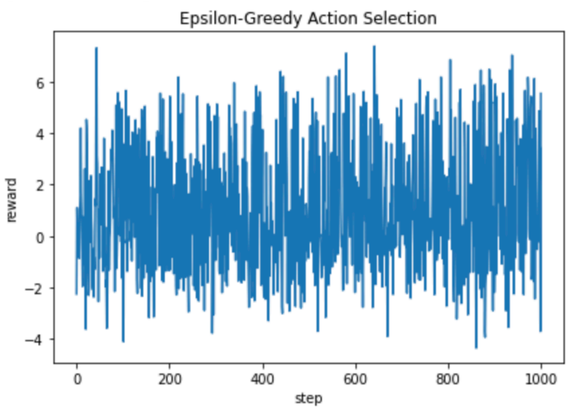
$$P(a_t = a) = \begin{cases} 1 - \epsilon & \text{if } a_t = \text{argmax}_a \, V_t(a) \\ \epsilon / N & \text{otherwise} \end{cases}$$

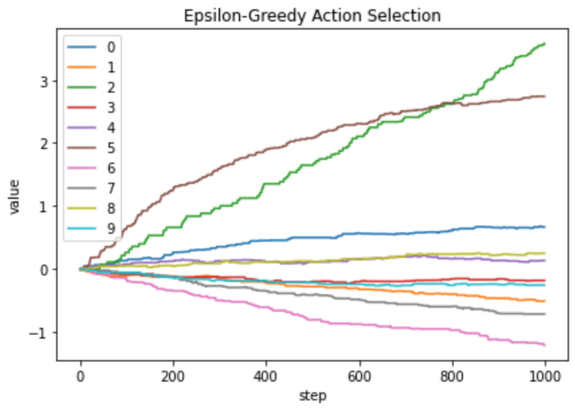
$\epsilon = 0.35$



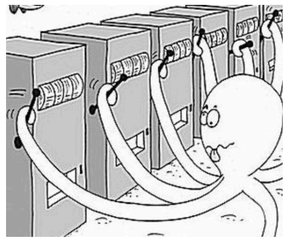


$\epsilon = 0.85$





Perfomance comparison

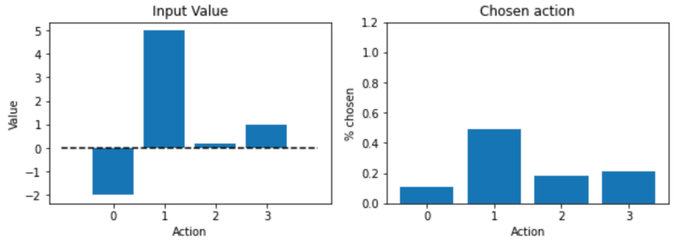


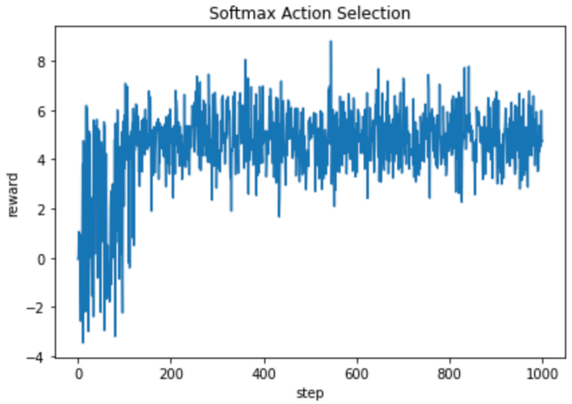
N arms = 10

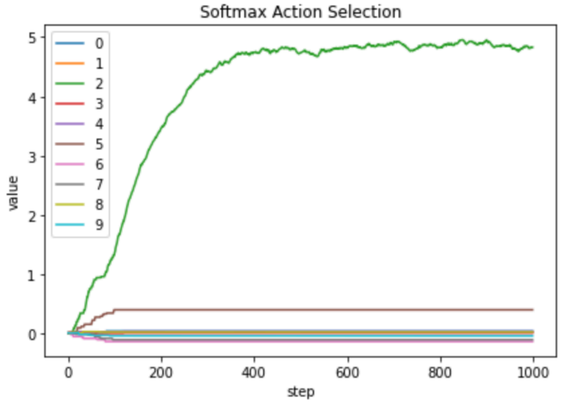
N simulations = 1000

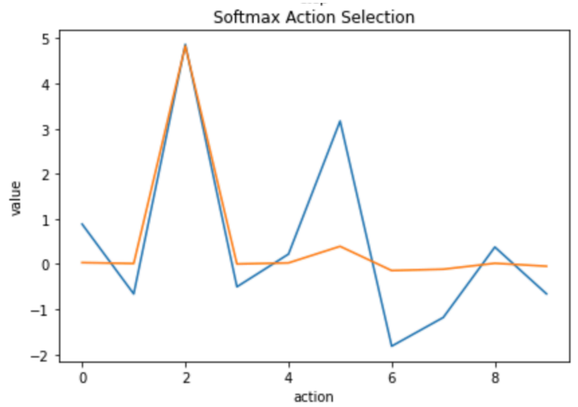
Softmax action selection:

$$P(a_t = a) = \frac{e^{V_t(a)\cdot\beta}}{\sum_{i=1}^{N} e^{V_t(a_i)\cdot\beta}}$$







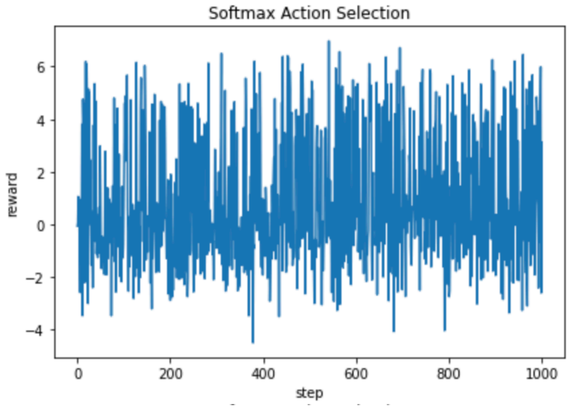


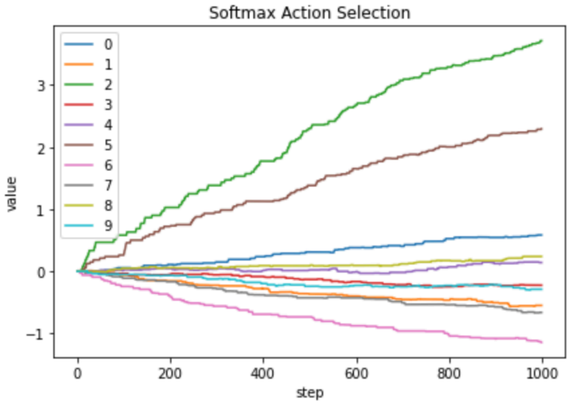
How will your choice of β affect these plots? (Here: $\beta = 2$)

Perfomance comparison

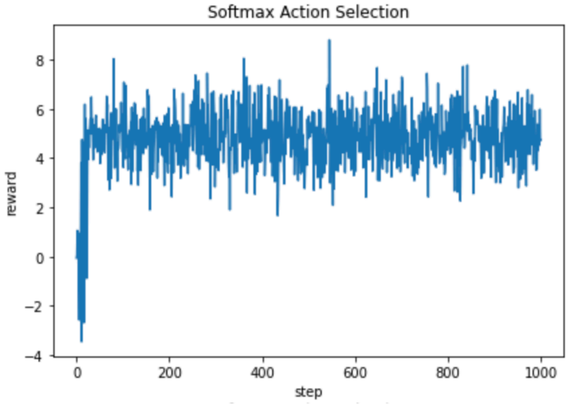
$$P(a_t = a) = \frac{e^{V_t(a)\cdot\beta}}{\sum_{i=1}^{N} e^{V_t(a_i)\cdot\beta}}$$

$\beta = 0.2$

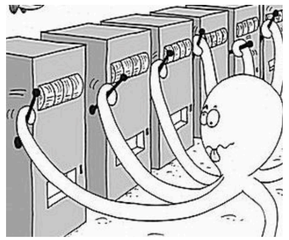




$\beta = 10$



Perfomance comparison

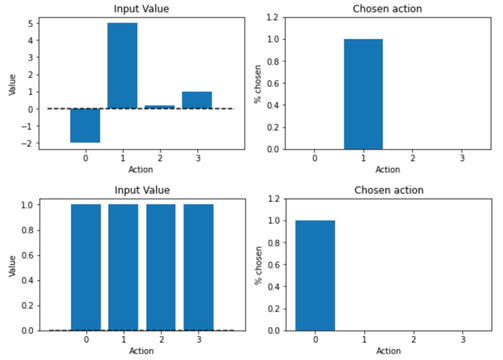


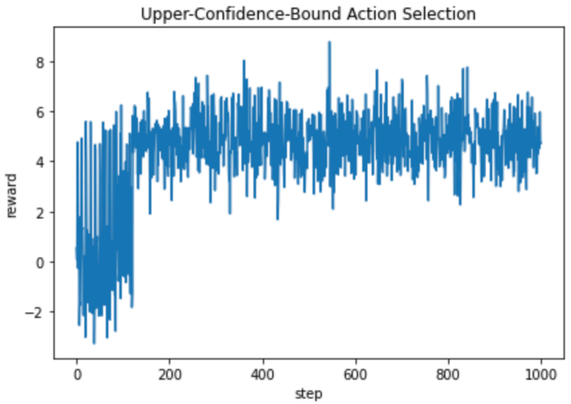
N arms = 10

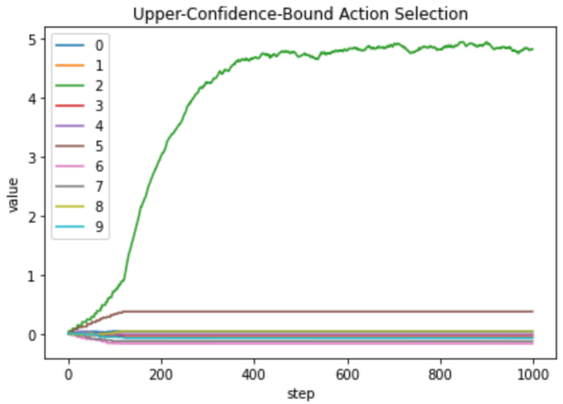
N simulations = 1000

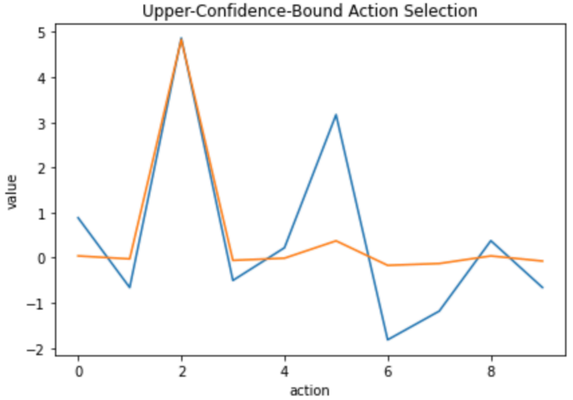
Upper-confidence-bound
(UCB) action selection:

$$P(a_t = a) = \text{argmax}_a[V_t(a) + c \cdot \sqrt{\frac{\ln t}{N_t(a)}}]$$







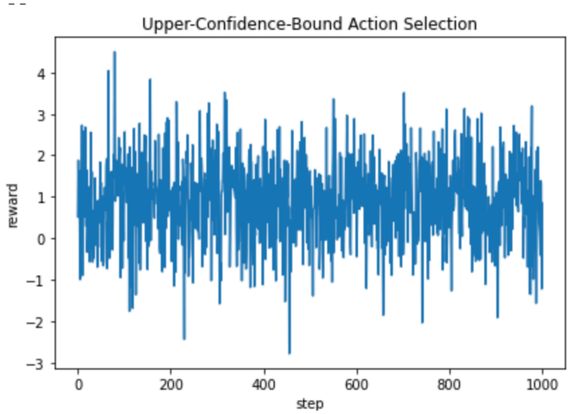


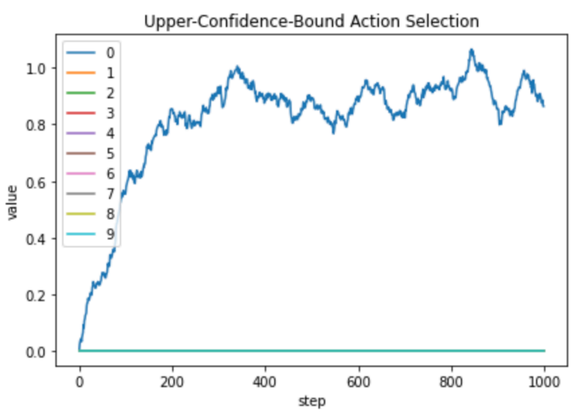
How will your choice of c affect these plots? (Here: $c = 5$)

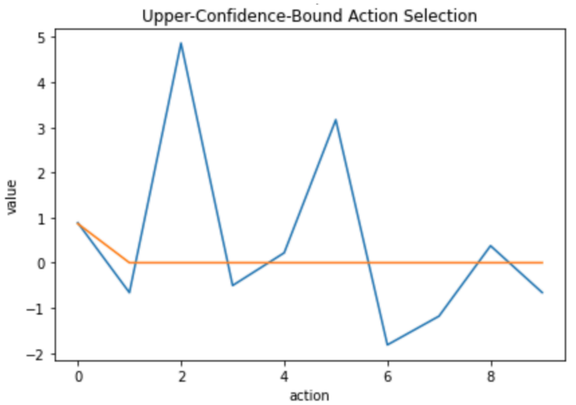
Perfomance comparison

$$P(a_t = a) = \text{argmax}_a[V_t(a) + c \cdot \sqrt{\frac{\ln t}{N_t(a)}}]$$

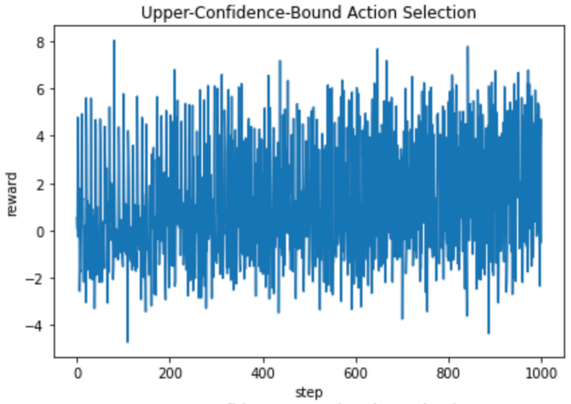
$c = 0$

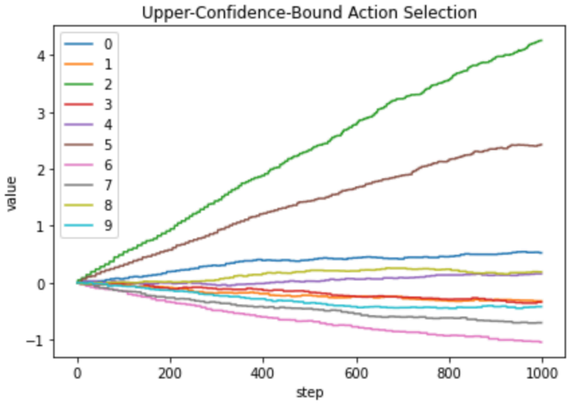


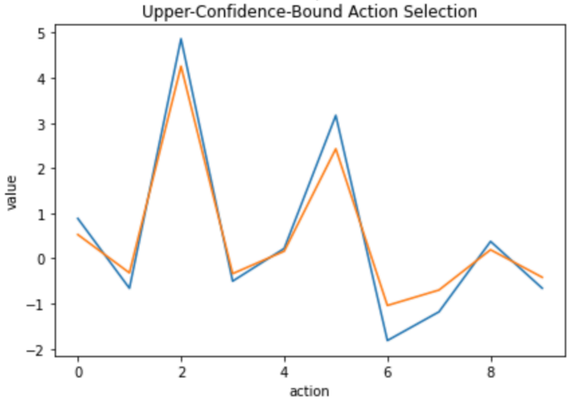




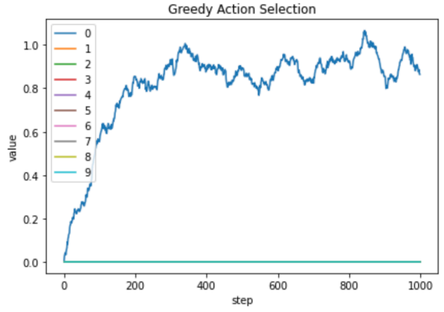
$c = 50$

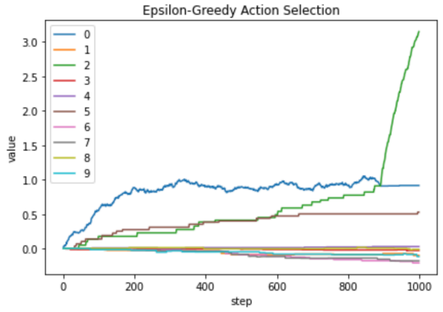


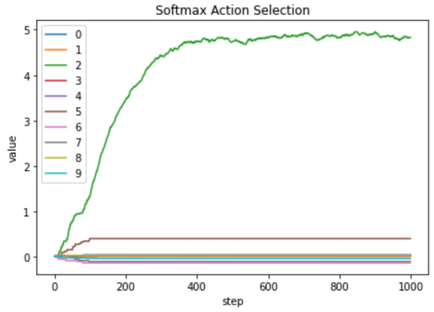


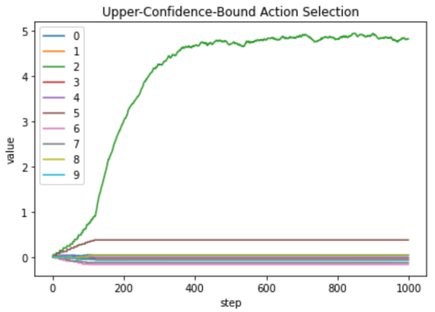


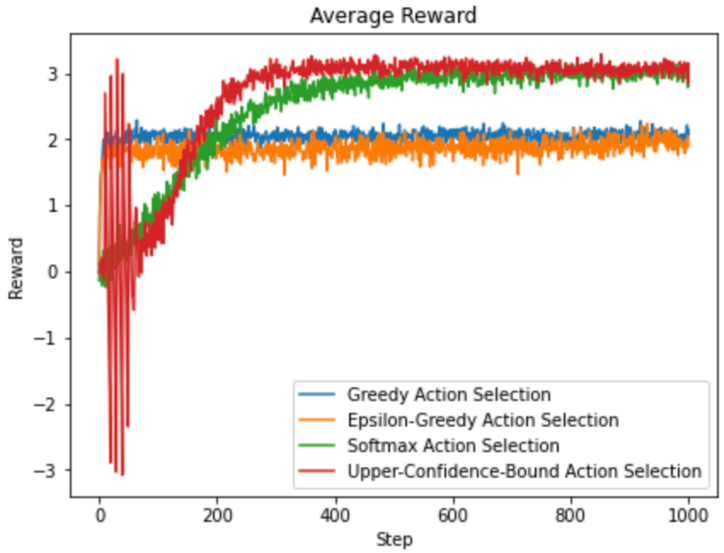
Perfomance comparison

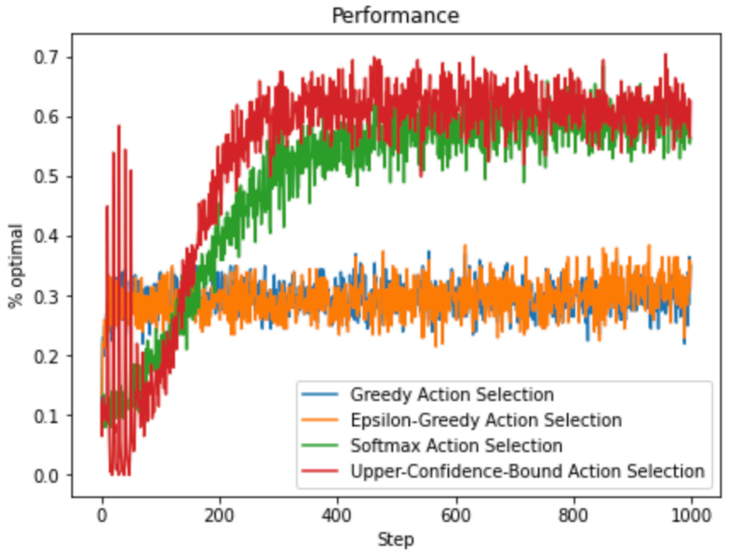












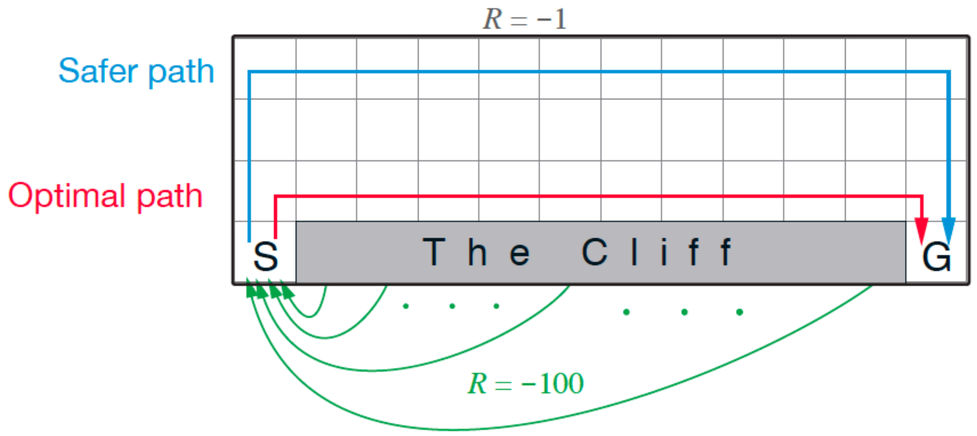
Q-Learning

Limitation of multi-armed bandit problems

Your current action does not influence what happens next!!

How can we solve sequential problems?

The textbook problem:
‘Cliff-World’



The rules:

- Agent has to move from start (S) to goal (G)
- Reaching the goal results in a positive reward of +10
- Falling off the cliff results in a negative reward of -100
- Any other state results in a negative reward of -1

What’s the problem the agent has to solve here??

Note the subtle introduction of the concept of ‘**transition probabilities**’ here
- implicit, later: explicit

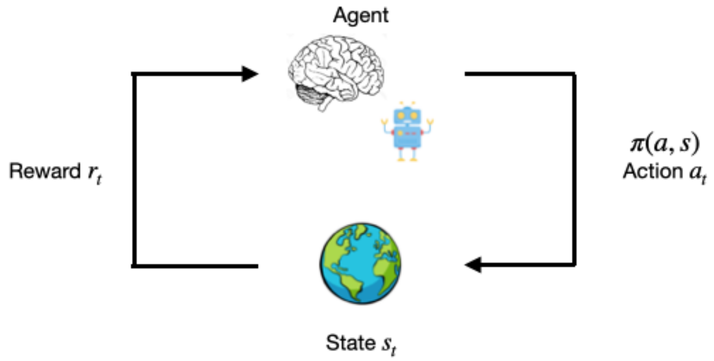
From classical to instrumental learning

TD Learning:

Prediction error

$$V(s_t) \leftarrow V(s_t) + \alpha \cdot (r + \gamma \cdot V(s_{t+1}) - V(s_t))$$

Learning rate Discount rate



Q-Learning:

Prediction error

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha \cdot (r + \gamma \cdot max_a Q(s_{t+1}, a_{t+1}) - Q(s_t, a_t))$$

Learning rate Discount rate

What's the difference between $V(s_t)$ and $Q(s_t, a_t)$?

What's is $max_a Q(s_t, a_t)$ doing?

Note that this is just an update rule - doesn't tell us how to select an action!

MDPs

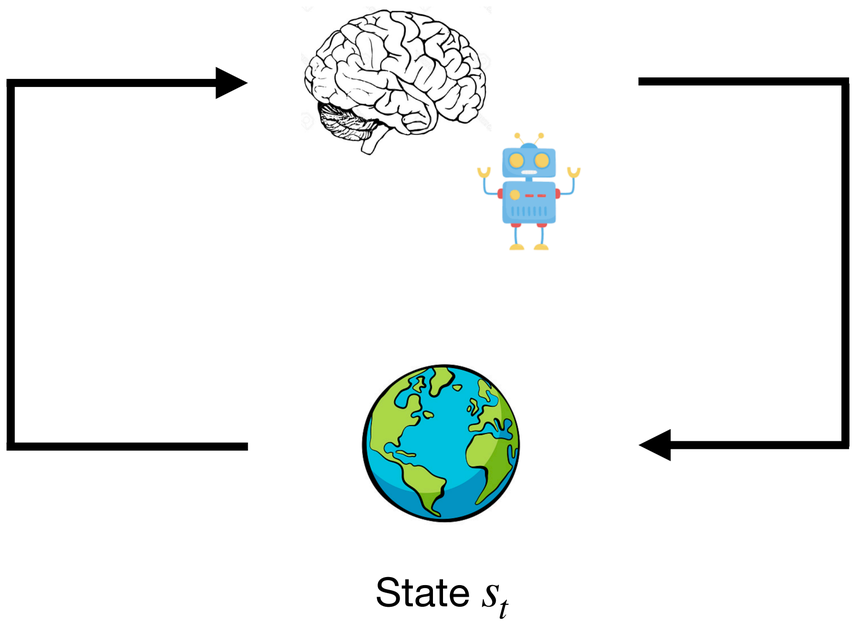
Basic setup: how do agents learn to act?

Based on a reward signal, agents learn **values of actions/states:**

$$V_\pi(s) = \mathbb{E}_\pi[R \,|\, s_0 = s]$$

Action is governed by a **policy**:

$$\pi(a, s) = P(a_t = a \,|\, s_t = s)$$



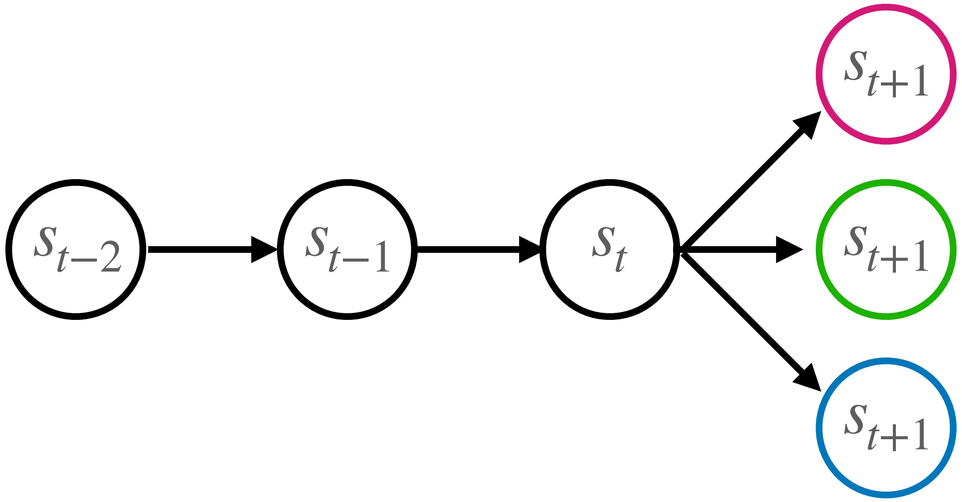
Agents can learn a **model of the environment** to make smarter decisions, e.g.:

$$P(s_{t+1} = s \,|\, s_t = s, a_t = a)$$

Markov Process → Markov Reward Process → **Markov Decision Process (MDP)**

Markov Process

Most RL problems are problems where agents face sequences of states:

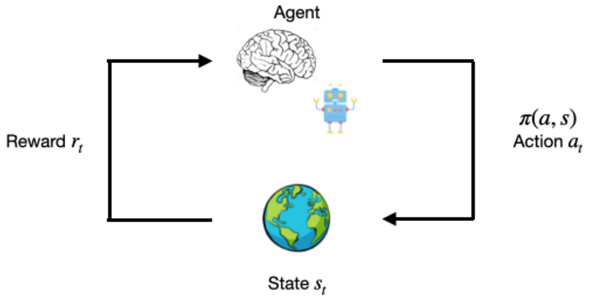


Fundamental property: **Markov property**

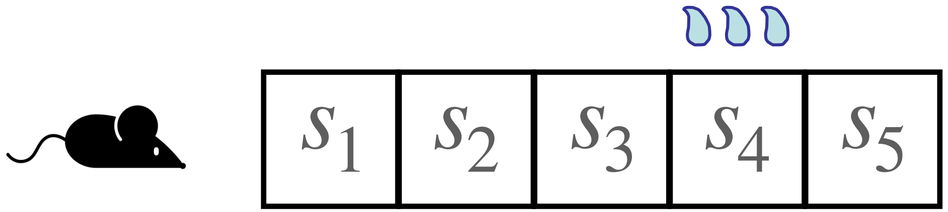
$$P(s_{t+1} = s \mid s_t, s_{t-1}, s_{t-2}, \dots) = P(s_{t+1} = s \mid s_t)$$

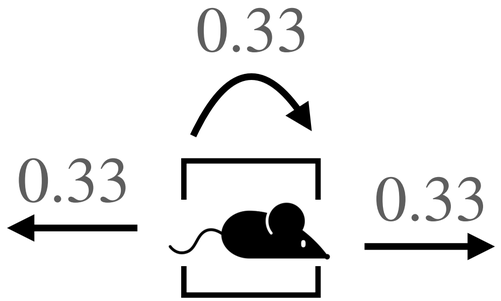
“The future is independent of the past given the present”

Markov Process

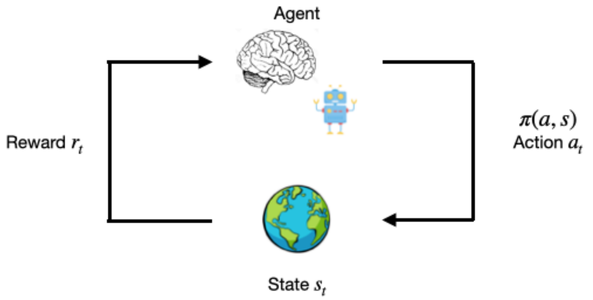


Let's assume a super simple problem:

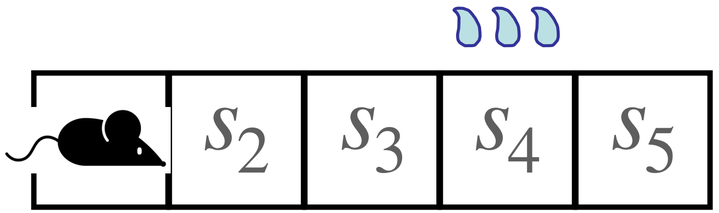


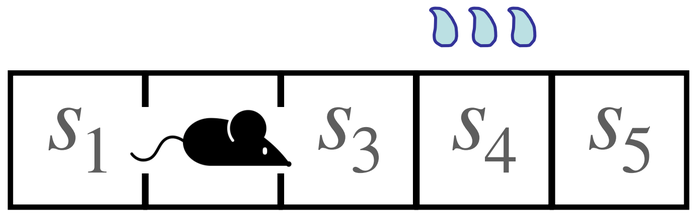


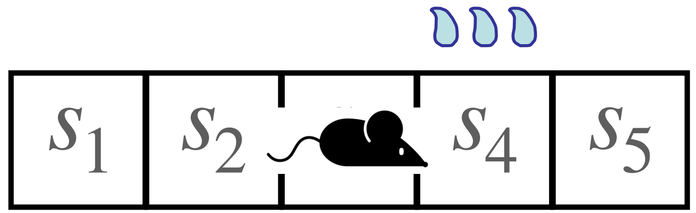
Markov Process

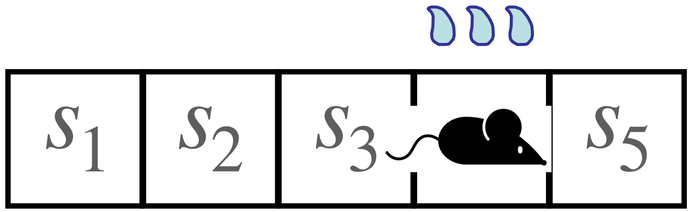


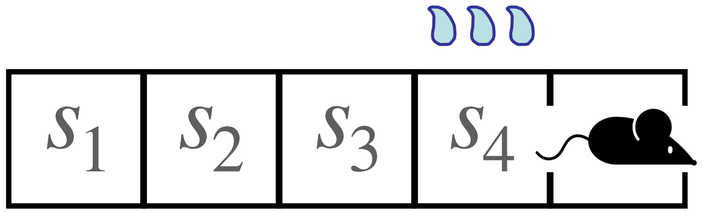
We can now define a **state space** S:



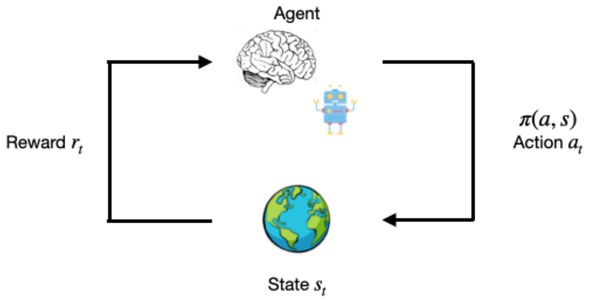




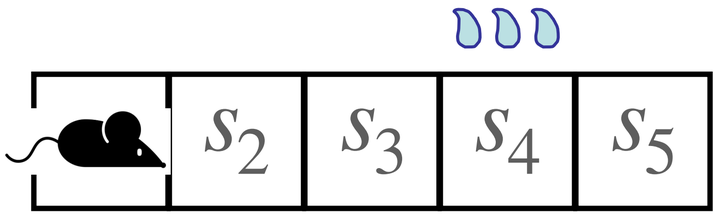




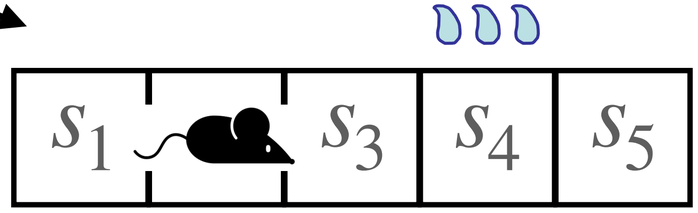
Markov Process

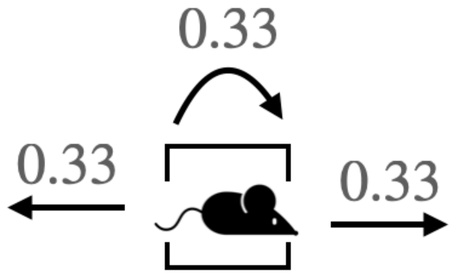


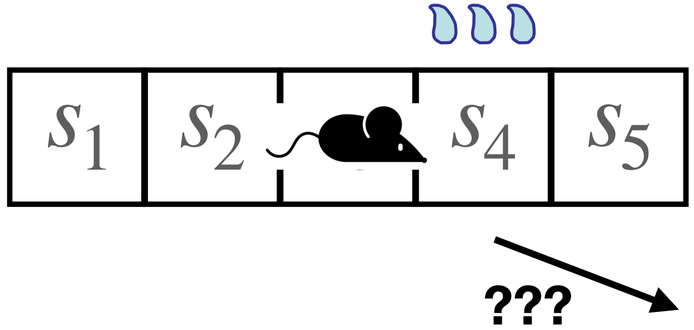
Does this problem have the **Markov Property?**



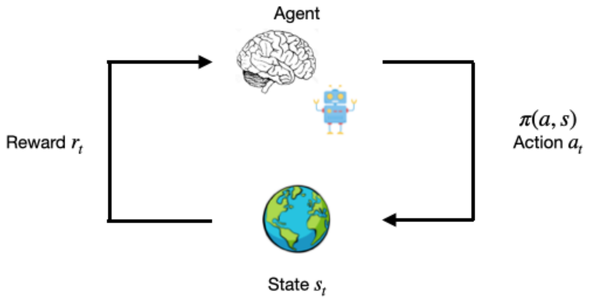
$$P(s_{t+1} = s \mid s_t, s_{t-1}, s_{t-2}, \dots) = P(s_{t+1} = s \mid s_t)$$





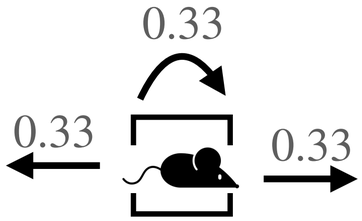


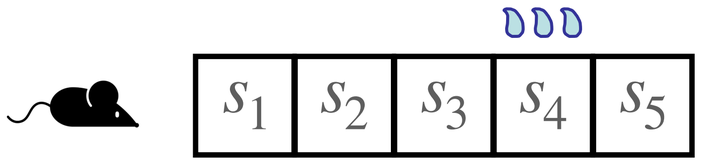
Markov Process



This allows us to define **transition probabilities** P:

$$P(s_{t+1} = s' \mid s_t = s)$$



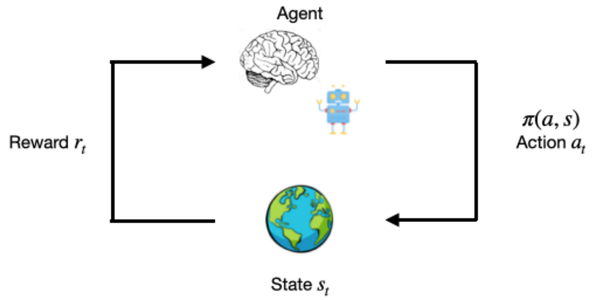


To

From

	s_1	s_2	s_3	s_4	s_5
s_1	0.66	0.33	0	0	0
s_2	0.33	0.33	0.33	0	0
s_3	0	0.33	0.33	0.33	0
s_4	0	0	0	1	0
s_5	0	0	0	0.33	0.66

Markov Reward Process

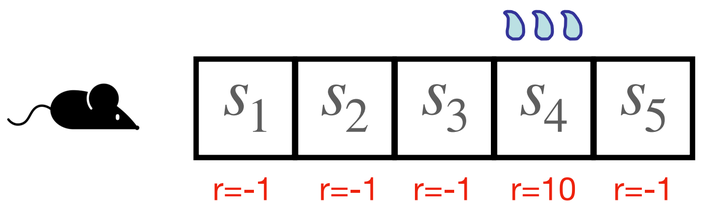


A **Markov Process** is defined based on

- A **State Space** S
- **Transition Probabilities** P $\quad P(s_{t+1} = s' \,|\, s_t = s)$

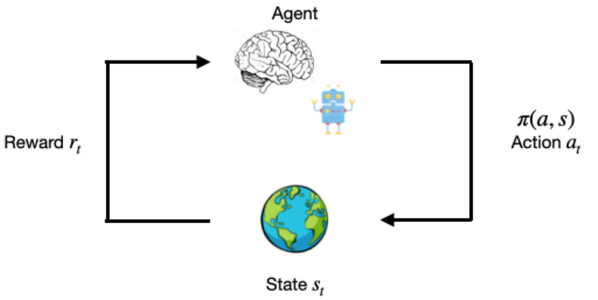
A **Markov Reward Process** is defined based on

- A State Space S
- Transition Probabilities P
- A **Reward Function** $R_s = \mathbb{E}[r_{t+1} \,|\, s_t = s]$
- A **Discount Factor** $\gamma \in [0,1]$



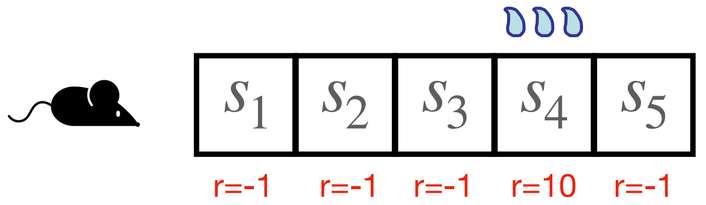
Allows to define **Return** $\quad G_t = r_{t+1} + \gamma \cdot r_{t+2} + \gamma^2 \cdot r_{t+3} + \ldots = \sum_{k=0}^{\infty} \gamma^k \cdot r_{t+k+1}$

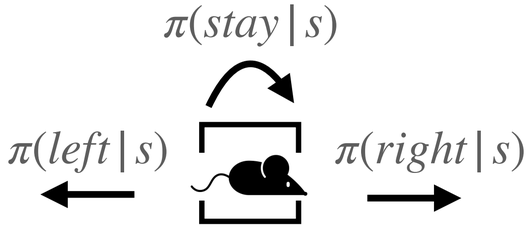
Markov Decision Process



A **Markov Decision Process** is defined based on

- A State Space S
- An **Action Space** A
- Transition Probabilities P
- A Reward Function $R_s = \mathbb{E}[r_{t+1} \mid s_t = s]$
- A Discount Factor $\gamma \in [0,1]$



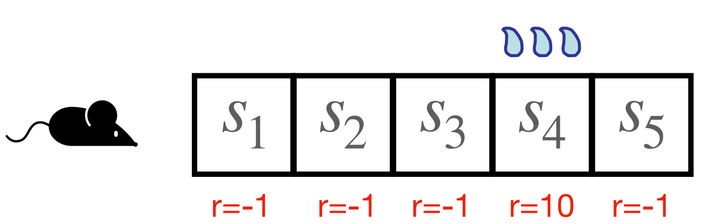


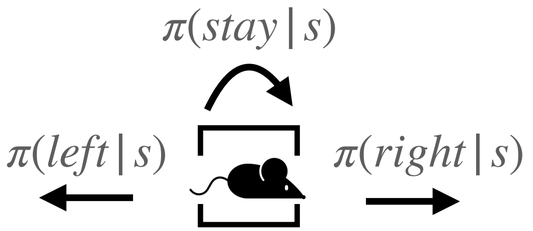
Actions are governed via a **policy**: $\pi(a, s) = P(a_t = a \mid s_t = s)$

MDPs basis for model-based RL

Allows to specify all environment dynamics for RL problem:

$$P(s', r \mid s, a) = P(s_{t+1} = s', r_{t+1} = r \mid s_t = s, a_t = a)$$



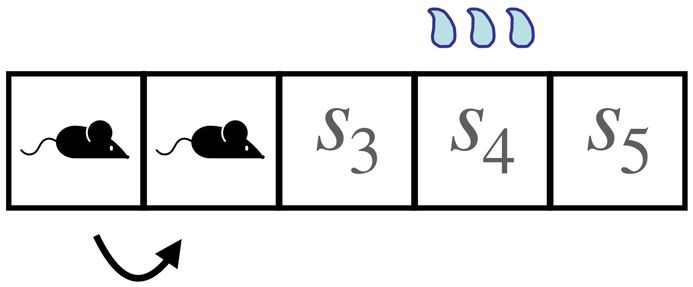


MDPs basis for model-based RL

$$P(s', r \mid s, a) = P(s_{t+1} = s', r_{t+1} = r \mid s_t = s, a_t = a)$$

Allows to specify useful thinks like **state-transition probabilities** (often T):

$$P(s' \mid s, a) = P(s_{t+1} = s' \mid s_t = s, a_t = a) = \sum_r P(s', r \mid s, a)$$



$$P(s' \mid s, right) = \begin{array}{c} \\ s_1 \\ s_2 \\ s_3 \\ s_4 \\ s_5 \end{array} \begin{array}{c} \begin{array}{ccccc} s_1 & s_2 & s_3 & s_4 & s_5 \end{array} \\ \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \end{array}$$
